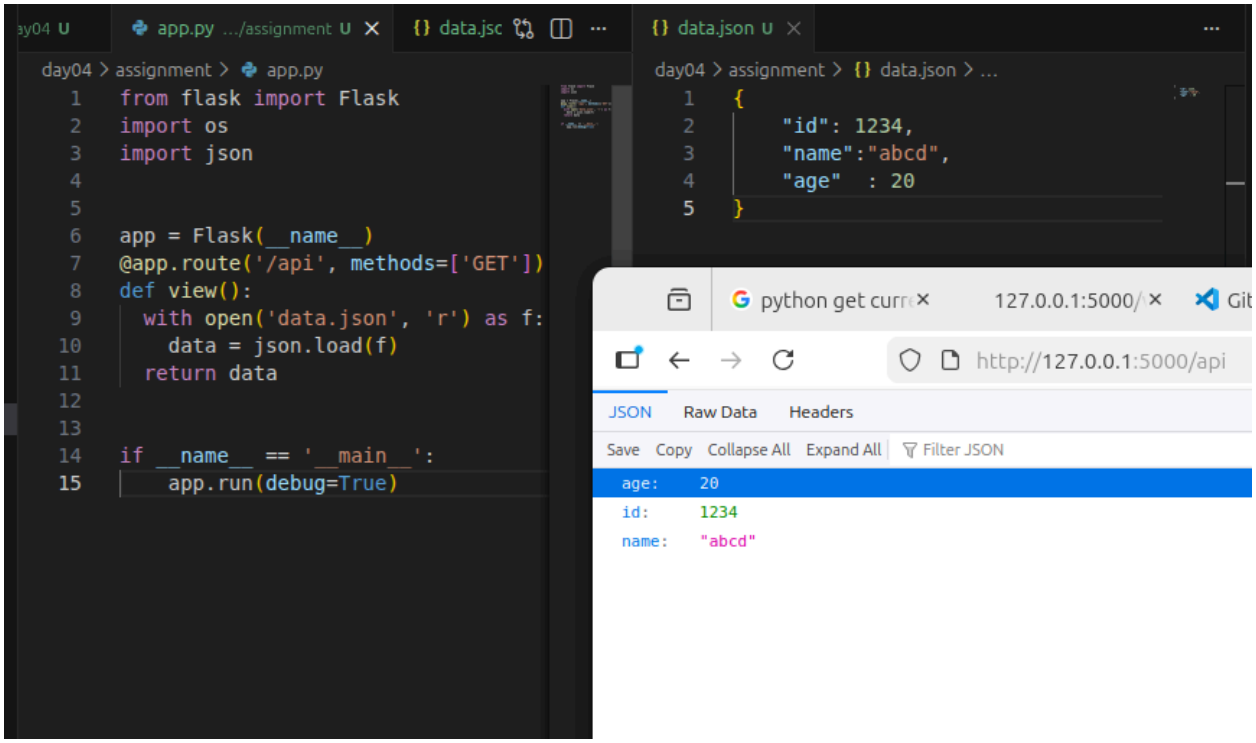
1. Create a Flask application with an `/api` route. When this route is accessed, it should return a JSON list. The data should be stored in a backend file, read from it, and sent as a response.

I have stored the data in the data.json(backend file) I was able to read the dta from with open('data.json', r) as f: -> now the data can be loaded using f
Next line i tried to load the data in the data variable using json.load method
Return the data to see in the browser



2. Create a form on the frontend that, when submitted, inserts data into MongoDB Atlas. Upon successful submission, the user should be redirected to another page displaying the message **"Data submitted successfully"**. If there's an error during submission, display the error on the same page without redirection.

I have created a templates/signup.html page, where i am taking username, email, password and confirm password. When user clicks on create account button it is redirected to signup page.

I have kept/invoked this html page on /home URI and used /signup URI to insert the data filled

on the signup.html in the mongo db. For connection to mongo db I have used the same .env file and load_dotenv() to load the mongo_uri, then used pymongo.mongoclient method to connect to my mongo db.
Used collection=db[‘database name’] -> to create the db in mongodb cluster.

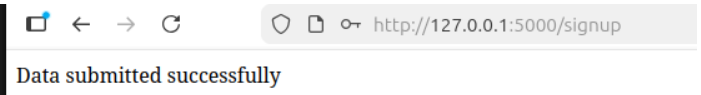
Initially i went to localhost or 127.0.0.1/home to update the info or lets say signup a user account. Once its done then route the traffic to signup method which will wait browser to reach the signup and once its reached it will insert/ send the data into my cluster

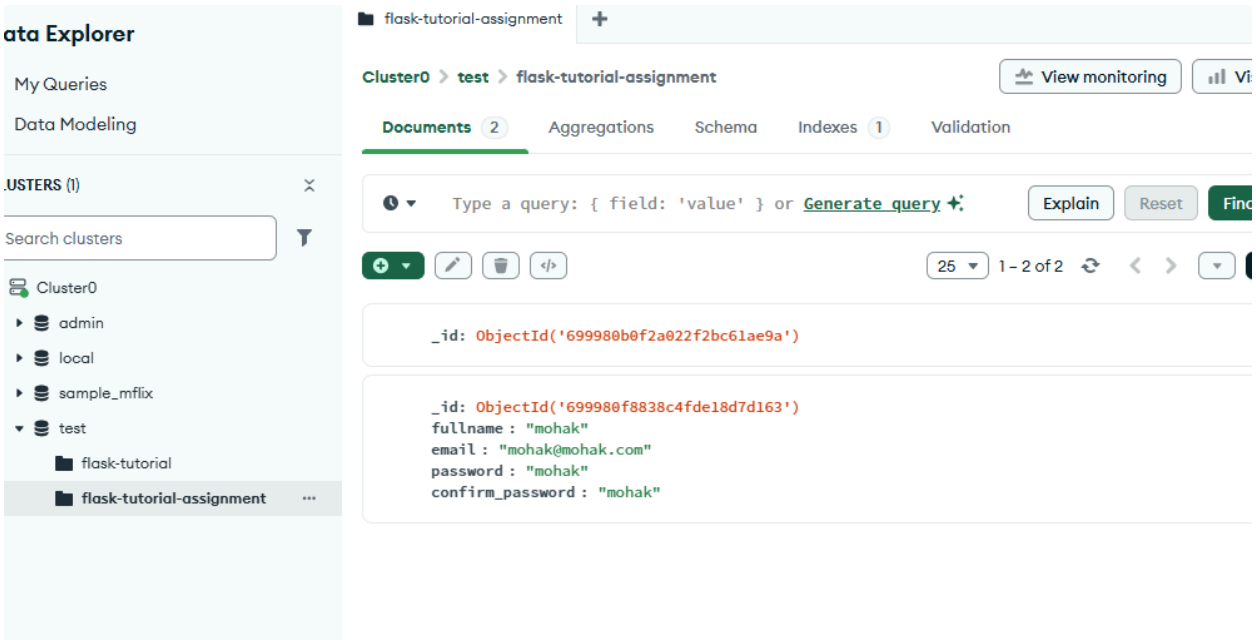
```python
load_dotenv()
MONGO_URI = os.getenv('MONGO_URI')
client = pymongo.MongoClient(MONGO_URI)
db=client.test
collection=db['flask-tutorial-assignment']

app = Flask(__name__)
@app.route('/api', methods=['GET'])
def view():
with open('data.json', 'r') as f:
    data = json.load(f)
  return data

@app.route('/home')
def home():
    return render_template('signup.html')

@app.route('/signup', methods=['POST', 'GET'])
def signup():
    name=request.values.get('fullname')
    form_data=dict(request.form)
    collection.insert_one(form_data)
    return "Data submitted successfully"
if __name__ == '__main__':
    app.run(debug=True)
```





Data submitted successfully
